Sea water density at various temperatures-----	88

## INTRODUCTION

The summaries of sea water temperatures and densities presented in this publication are based on observations made at locations along the Pacific coast of North and South America and Pacific Ocean islands through the year 1969. The sea water temperatures and densities were observed primarily at tide stations which, in the United States and possessions, were maintained by the National Ocean Survey (formerly Coast and Geodetic Survey), often with the cooperation of other organizations. The data for six places on the California coast, namely La Jolla, Balboa, Port Hueneme, Pacific Grove, Southeast Farallon Island and Blunts Reef Lightship were supplied by the Scripps Institution of Oceanography. The data for places in Chile were supplied by the Departamento de Navegación e Hidrografía, República de Chile. Other observations in Latin America were obtained through cooperation with the Inter American Geodetic Survey. Data for the Philippine Islands were supplied by the Bureau of Coast and Geodetic Survey of the Republic of the Philippines. For places in other countries the National Ocean Survey (formerly Coast and Geodetic Survey) derived the data from observations made by organizations in the particular country.

Table 1 presents monthly means and annual means and extremes of the surface water temperatures and densities for each year of observation after 1964. Earlier observations are combined in five-year groups. For each station at which the series of observations covered two or more years, the following monthly values are presented: the mean of the monthly means, the maximum observed, the mean of the monthly maxima, the mean of the monthly minima and the minimum observed.

When an asterisk appears in either extreme temperature column in Table 1, it indicates that the extreme may have been exceeded if observations had been available for all months in which the maximum or minimum normally occurs. If observations are not available for any month in which the yearly maximum or minimum may have occurred, the extreme has been omitted. For densities, the yearly extremes are from the months of the year for which means are given. If they are from an incomplete year, they are followed by an asterisk.

The temperature data given in degrees Celsius are based on thermometer readings made in a sample of water drawn by bucket from a foot or two below the surface. They can be converted to degrees Fahrenheit by means of Table 2.

The density of any substance is defined as the mass per unit volume. The density of sea water, as observed, depends not only upon the amount of soluble matter held in solution but also upon the temperature of the water at the time the reading was made. It is necessary, therefore, to reduce the observed densities to some standard temperature in order that they may be comparable. In this publication the observed densities have been reduced to a standard temperature of 15°C (59°F). The density of pure water at a temperature of 15°C is taken as 0.9991. The density values obtained by using a hydrometer were reduced to the standard temperature by using the tables given in C&GS Special Publication No. 298.

Densities in Table 1 are expressed in terms of the Greek letter sigma with a subscript that refers to temperature and is called a sigma-t ( $\sigma_t$ ) value. Thus:  $\sigma_{15} = (\rho_{15} - 1) 1000$  where  $\rho_{15}$  is the density of sea water at 15°C (59°F) referred to pure water at 4°C (39.2°F) as unity. For example: If sea water has a density at 15°C of 1.0268,  $\sigma_{15} = 26.8$ . The actual density of the water may vary from a little less than unity for fresh water at a temperature other than 4°C to approximately 1.0410 for the heaviest sea water.

The salinity of sea water, denoted by the symbol  $^{\circ}/oo$ , is defined as the number of grams of salts contained in 1000 grams of sea water. Table 3 gives the salinity corresponding to different values of density at the standard temperature of 15°C.

## INTRODUCTION

The observations are usually made once each weekday at whatever time the observer attends the gage. At some stations situated within or near the entrance of an estuary, the temperature or density varies with the stage of tide or with the direction of the tidal current. It may be assumed that in the course of a month or more the distribution of observations is fairly uniform over all phases of the tide.

The mean temperature and density curves are derived from the monthly means given in Table 1 and show graphically the seasonal variation for many places.

For some practical uses of density data, it is more important to know the density at the temperature apt to be encountered than at the standard temperature. The graph, Sea Water Density at Various Temperatures, provides for converting density at 59°F (15°C) to density at other temperatures.

The following Coast and Geodetic Survey publications on sea water temperatures, salinities and densities are also available:

C&GS Publication 31-1, Surface Water Temperature and Density,  
Atlantic Coast, North and South America (Third Edition)  
1968, \$1.00.

C&GS Special Publication No. 298, Sea Water Temperature and  
Density Reduction Tables, 1953, 25 cents.

## Sea Water Density at Various Temperatures

The purpose of this graph is to provide the density of sea water at any temperature apt to be encountered when the density at the standard temperature of 59°F (15°C) is known. To convert a density at 59°F (15°C) to density at another temperature, enter the graph horizontally from the left with the known density and downward from the top or upward from the bottom with the desired temperature; the position of the point of intersection with respect to the curves gives the density at the desired temperature. Interpolate between curves when necessary. For example, by this method, water having a density of 1.0162 at 59°F is found to have a density of 1.0124 at 85°F. The densities are referred to the density of fresh water at 4°C (39.2°F) as unity.
